"New Star" to appear in next few months  
About every 80 years a bright "nova" or seemingly new star appears in the Northern Crown (Corona Borealis) constellation. A dim pair of stars orbiting each other suddenly brightens when enough material from the red giant star shifts to the white dwarf star and it explodes. The nova is expected before September.

Why are the Sun, Moon, and Planets in a line?

Earth and the visible planets orbit the Sun in nearly the same plane (the ecliptic plane), and the Moon orbits the Earth in close to the same plane. So we see the Sun, Moon, and planets in one rough line across the night sky (the ecliptic). A solar eclipse occurs when the Moon passes in front of the Sun along the ecliptic.

The Ecliptic-Path of Sun, Moon and Planets across Sky  
With Mercury and Venus lost in the Sun's glare, and Jupiter, Mars, and Saturn visible in the pre-dawn sky, no planets are visible in the evening sky.  
Look for the bright stars Procyon in Canis Minor, Pollux and Castor in Gemini, Regulus in Leo, and Spica in Virgo. Almost half of the waxing Moon's disc is illuminated.

Looking West

Solstice = "Sun Stationary"  
The Summer Solstice occurs on June 20th when the North Pole is most tilted toward the Sun. The Sun has been shifting higher in the Summer Solstice. Sunsets and sunrises will be later in the Fall Equinox.

Sun direct over head at noon on the Tropic of Cancer

Sun direct over head all day above Arctic Circle

Sun direct over head all day below Antarctic Circle
